To adequately define the noise problem and set a good basis for the control strategy, the following factors should be considered: type of noise noise levels and temporal pattern frequency distribution noise sources (location, power, directivity)

Since the late 1940s, scientists and engineers have been working on ways to control noise from machinery. In the 1970s, the emphasis was on engineering controls in the workplace, but since then the focus has shifted because OSHA has not enforced the requirement for engineering controls and because industry leaders have failed to take into account the risk to hearing when purchasing equipment.

Noise control engineering is concerned with the application of basic acoustics and vibration theory to reduce noise in practical situations. The noise control engineer needs to know how to set targets, how to characterise and quantify noise sources, and how to reduce noise either at source or, more commonly, in the transmission path.

One of the first means of engineering controls is to interrupt the path of the noise from the source to the worker. This is best achieved where higher frequencies are involved by blocking the path through acoustical insulation that is effective for a specific frequency range.

Designer-NOISE® is a software program designed to allow for quick and accurate predictions of noise levels on surface ships and other stiffened plate structures. Octave-band and overall A-weighted noise levels are calculated based on sound propagation from machinery, propeller, and wave slap sources via airborne and structureborne paths.

The exposure to noise can be reduced by eliminating the source of noise (if possible), substituting the source with a quieter one, applying engineering modifications, using administrative controls, and by using protective equipment. The best way to reduce exposure to noise is to engineer it out at the design stage.
